But we can ask how the risk of such an extreme event occurring has changed due to external factors

Possible outcomes of an attribution study:

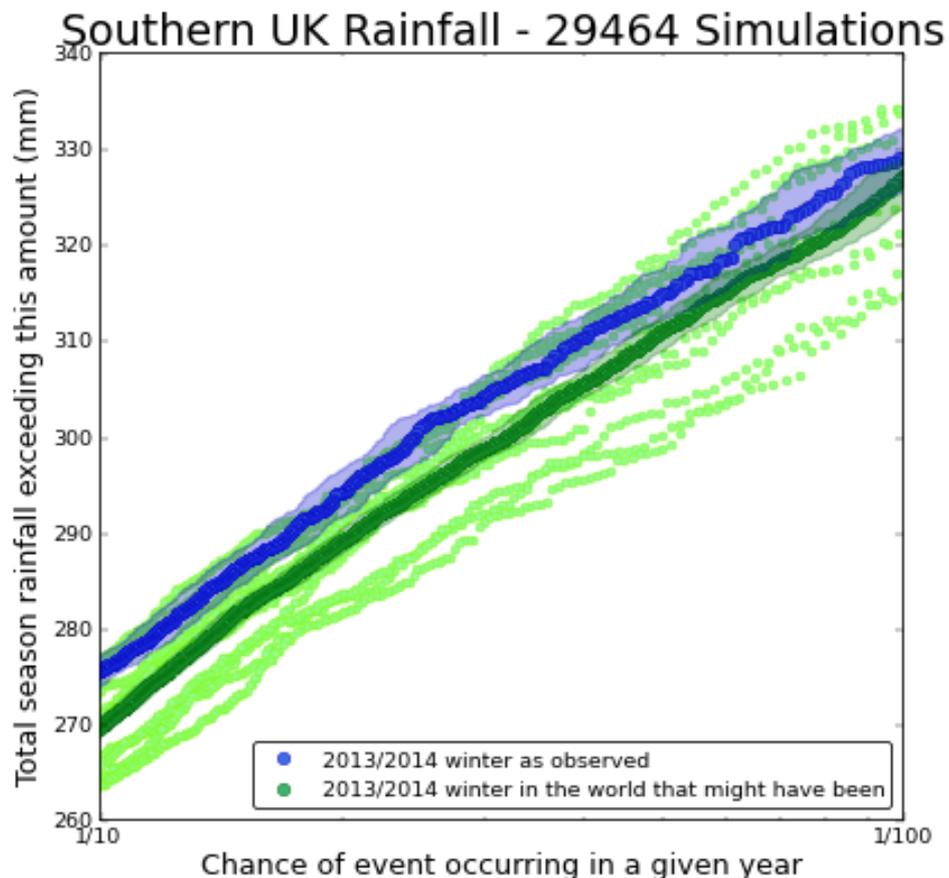

1. The event was made more likely due to anthropogenic climate change
2. The event was made less likely due to anthropogenic climate change
3. Anthropogenic climate change did not alter the frequency of occurrence of the event
4. With our current understanding and tools we cannot assess whether and how the event was influenced by anthropogenic climate change

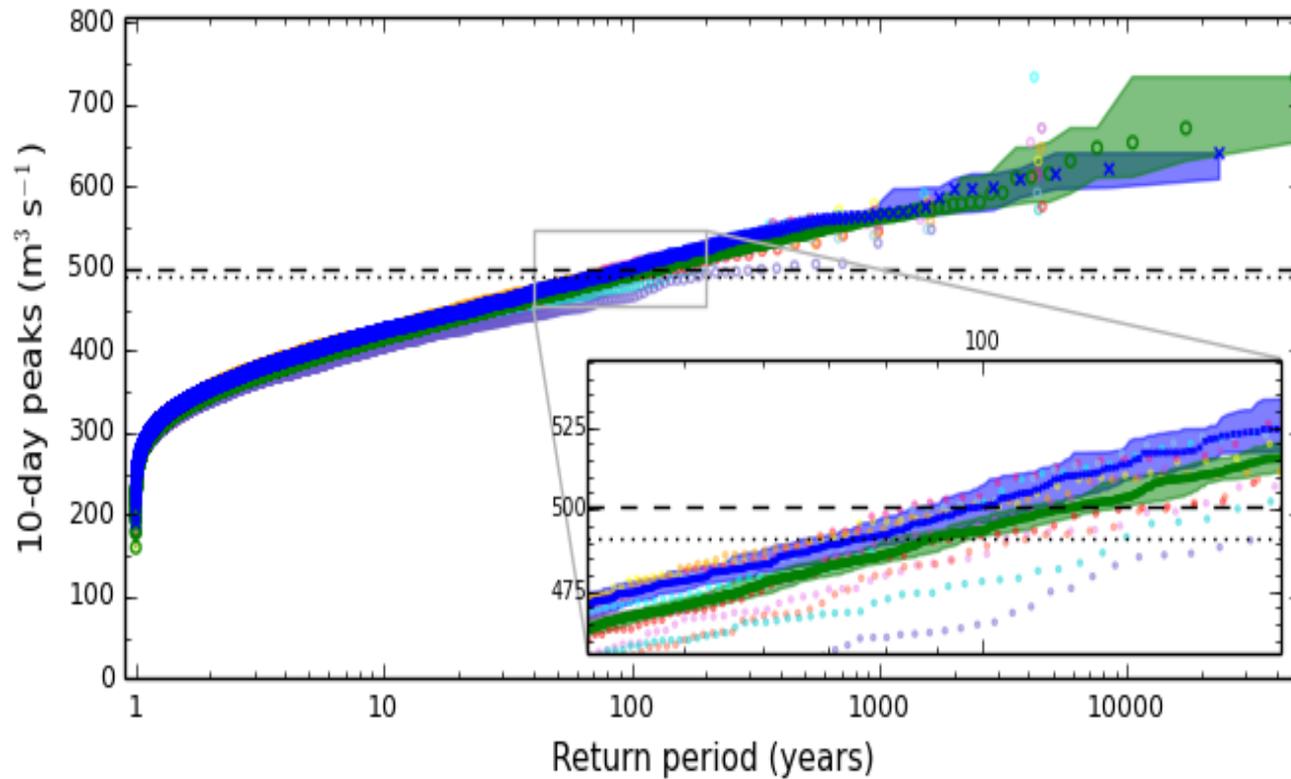

The highest precipitation ever recorded in winter in Oxford

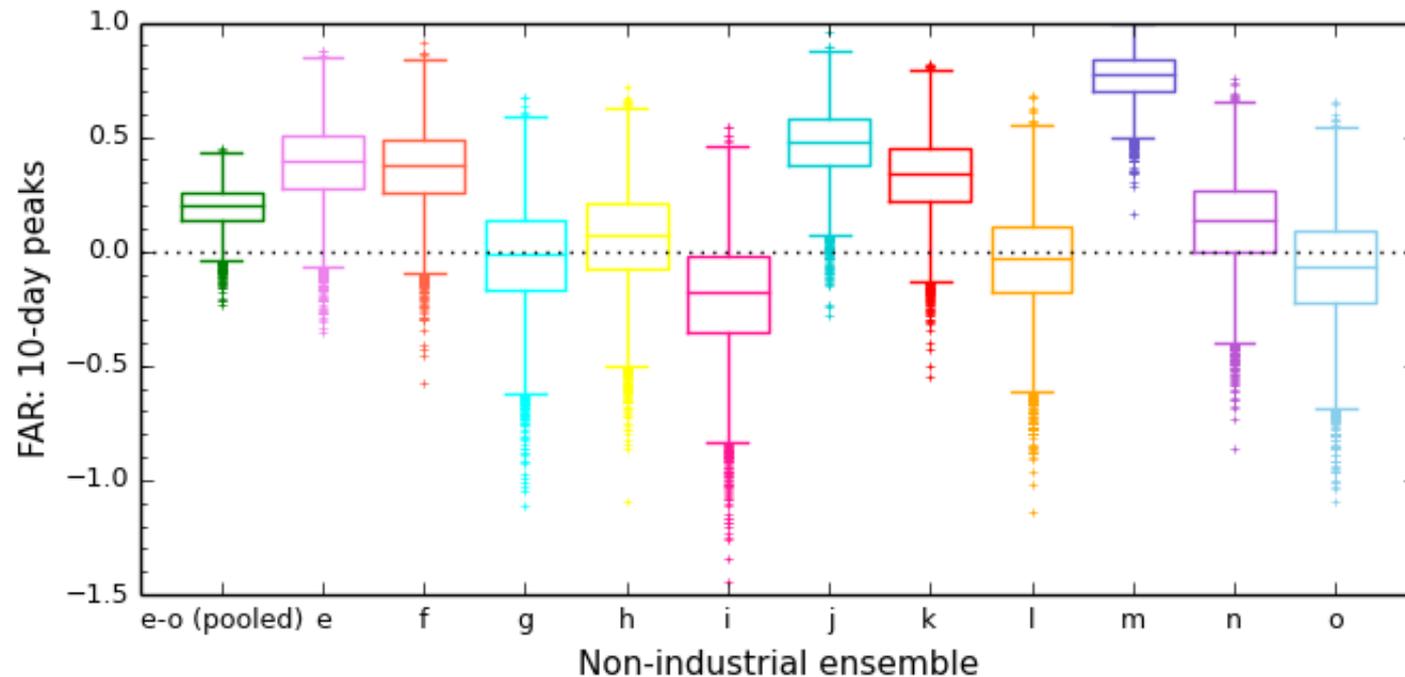

25% increase in the risk of what was a 1 in 100 year event in the world that might have been

10-day peak river flow in the Thames catchment

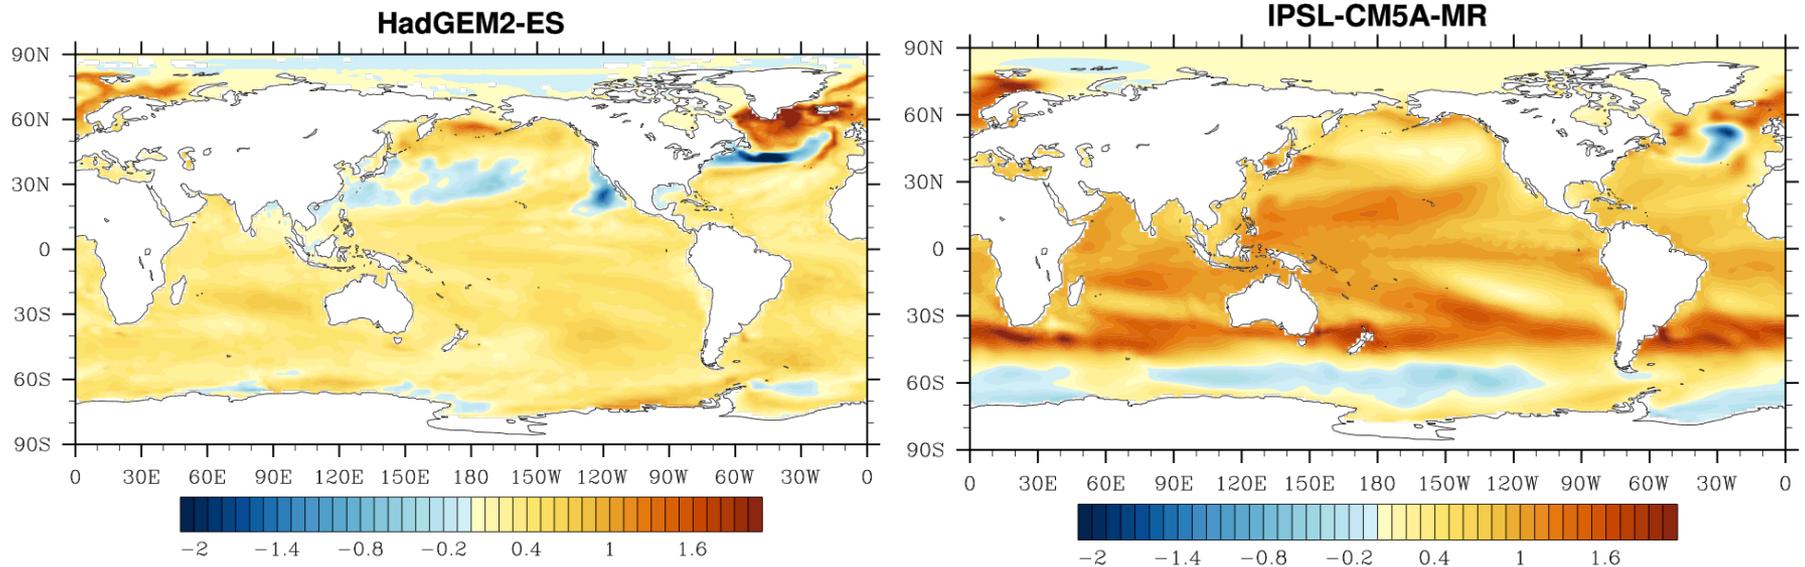

FAR for river flow depending on the SST pattern removed

The world that might have been

2 of 11 different SST patterns removed from observation

DJF SST response pattern to anthropogenic forcing for the HadGEM2-ES (left) and IPSL-CM5R-MR (right) models

The weather@home strategy

- ◆ Use very large ensembles of regional models (HadRM3P) embedded in an atmosphere-only global model (HadAM3Pxxxx)
- ◆ Remove different patterns of warming from the SST forcing to create counterfactual “worlds that might have been” (and different strategies)
- ◆ Use observed SSTs and seasonal forecasts SSTs
- ◆ Use multiple lines of evidence when making attribution statements
- ◆ Scrutinise our methods and models
- ◆ **Invite you to contribute with your methods when we want to make attribution statements**
